Water Chemistry and Isotope Data	Water Chemistry and Isotope Data - SWAS(C)
Points are added if water sample results indicate detectable levels of nitrates or nitrites, volatile organic chemicals (solvents, fuel components), and/or synthetic organic chemicals (pesticides or herbicides). Tritium monitoring is included as a voluntary means of age-dating water. Generally, the older the water, the more protected the source. Point Range 0-50. (50 points = MCL violation) Susceptibility is Very High if contaminants exceed the Maximum Contaminant Level (MCL).	Nitrates and Nitrites: 10 SOC.VOC: 5 Tritium Results: 0 Total SWAS(C) Points: 15
	Isolation from Contamination - SWAS(S)
<b>Solation from Sources of Contamination</b> Points are added based on the number and type of potential contaminant sources within he isolation distance (75 ft. from standard or 800 ft. from major contaminant sources). Examples of standard sources are septic tanks, sewer lines, and storm drains. Examples of major sources are chemical and fuel storage, landfills, lagoons, and known plumes of groundwater contamination.	Major Sources from 75 - 800 ft: $0 \times 10 = 0$ Major Sources within 75 ft: $0 \times 20 = 0$ Standard Sources within 75 ft: $0 \times 10 = 0$ Known Sources within 800 ft: $0 \times 25 = 0$
	Total SWAS(S) Points: 0
Source Water Assessment Score (SWAS)	Source Water Assessment Score - SWAS
The total SWAS is factored with the Geologic Sensitivity to determine the overall susceptibility to contamination.	$\frac{9}{\text{SWAS}(G)} + \frac{25}{\text{SWAS}(W)} + \frac{15}{\text{SWAS}(C)} + \frac{0}{\text{SWAS}(S)} = \frac{49}{\text{SWAS}(S)}$
Susceptibility Determination	Susceptibility Determination
Susceptibility is a means to identify the relative potential of contamination for public water supply sources.	Based on the above compilation of source geology, well construction, water chemistry, and potential contaminant sources, this public drinking water supply is determined to have a Susceptibility Rating of:
	Moderate
